

LEAP results

September 1, 2013

This document describes the results we have obtained applying LEAP to a set of examples. The results are divided into two sections. The first section presents the sequential examples, mainly based on sequential skiplists. The second section presents the concurrent examples based on a ticketing system and lock-coupling lists.

Each section presents two tables. The first table describes each invariant candidate and the decision procedures that were used in order to verify them. The second table presents the analysis time for each invariant candidate.

Consider the first table of each section. A parametrized formula in the concurrent case will consist on a formula parametrized by a number of threads identifiers. The number of thread identifiers parametrizing the invariant candidate is the *index* of the formula and it is shown in the second column of these tables. Depending on the proof rules we are applying (B-INV, P-INV, SP-INV, ...) and the length of the program, a number of verification conditions (VCs) are generated. The number of generated VCs that needs to be verified as valid are shown in the third column. A feature of LEAP is the possibility of applying tactics in order to simplify the VCs that needs to be analyzed. Applying a tactic on a single VC may simplify it, or it may produce many new VCs that subsumes the original VC. However, the idea is that all new VCs obtained through tactics are simpler to analyze than the original one. Thus, the number of actual final VCs (or queries as we call them) may be more than the original number of VCs, and their number is depicted in the forth column of the table.

The final eight columns of the table contains the number of calls performed to each decision procedure in order to solve all the queries. We use the following decision procedures:

- A FO decision procedure, which reasons using only first order logic and information about the program counter. This DP usually solves simple queries in almost no time, speeding up the verification process.
- A Num decision procedure, which is capable of reasoning about Presburger Arithmetic with sets of integers.
- A TLL decision procedure, capable of dealing with concurrent lock-coupling single-linked lists.
- A TSL decision procedure, which deals with skiplist of arbitrary height.
- A set of TSLK₁, TSLK₂, TSLK₃ and TSLK₄, which refers to decision procedures capable of reasoning about skiplist with a fixed number of levels (1, 2, 3 and 4 respectively).

For all the cases not involving the use of TSL, notice that the sum of calls perform to all decision procedures is equal to the number of generated queries. In the case of the skiplist example involving TSL, notice that the sum of calls performed to FO and TSL is equal to the number of generated queries. This means that each query is solved through first order logic reasoning, or if not possible, through a call to the TSL. However, because of how TSL decision procedure works, this may require multiple calls to Num (when guessing arrangements) as well as many calls to simpler decision procedures such as TSLK₁, TSLK₂, TSLK₃ and TSLK₄.

Now, consider the second table of each section. This table shows the time required in order to analyze all generated VCs for each invariant candidate. The first column presents the name of the invariant candidate and the second column the number of generated VCs (which matches with the first table). Then, we present three columns showing the time required to analyze the VC which required less time, most time and the average time required to analyze each VC. The sixth column shows the total time employed by the decision procedures to analyze all VCs. The final column denotes the total it requires LEAP in order to analyze and verify the invariant candidate. This value is greater than the one shown in the previous column as it includes, in addition to the time employed by the decision procedures, the time required to parse the program, the invariant candidates, generate the VCs, apply tactics, transform the intermediate formulas, etc. All the times shown in these tables are in seconds.

1 Concurrent examples
